Testing Statistical Hypotheses Of Equivalence

Equivalence tests are a variation of hypothesis tests used to draw statistical inferences from observed data. In equivalence tests, the null hypothesis is defined as an effect large enough to be deemed interesting, specified by an equivalence bound. The alternative hypothesis is any effect that is less extreme than said equivalence bound. The observed data is statistically compared against the ...

When the objective of a statistical hypothesis test is to conclude that groups are equivalent, an equivalence test should be utilized. An equivalence test forces us to identify from a practical perspective how big of a difference is important and puts the burden on the data to reach a conclusion of equivalence.

The hypothesis is tested as a composite of two one-sided t-tests (TOST), $H_0 1$ tests the hypothesis that mean difference is less than the lower bound of the equivalence interval, test $H_0 2$ that the mean difference is greater than the upper bounds of the equivalence interval.

For example, consider the difference between a 2-sample t-test and a 2-sample equivalence test. You use a 2-sample t-test to test whether the means of two populations are different. The hypotheses for the test are as follows: Null hypothesis (H_0): The means of the two populations are the
